BIOINFORMATICS Fast Alignment

Mark Gerstein Yale University gersteinlab.org/courses/452 (last edit in spring '19, MG pack #5)

Computational Complexity

- The dynamic programming alignment algorithm is O(n m) ~ O(n²) in speed and memory
- O(n²) in speed and memory is not good enough for Mimportant applications
- database search
- short read alignment to reference genome

gersteinlab.org Yale, 2012. Gerstein, Σ (C) 2

Μ

Fast sequence alignment

- Alignment via dynamic programming (NW/SW)
 - useful for aligning the small numbers of protein, DNA sequences available in the 1980s
- 1990s hundreds of thousands of protein sequences
- Today thousands of genome sequences
- => need for faster, more coarse-grained alignment methods
 - ◊ first application: find your favorite protein in a sequence database
 - next-gen seq application: align millions of short reads to a reference database

Computational Complexity

- Designing algorithms involves a trade-off between calculation time and memory usage & sensitivity
- Steps that can be pre-calculated and stored efficiently in memory speed up the algorithm
- FASTA (hashing the query)
- BLAST (more efficient query hashing)
- BLAT (hashing the DB)
- BWA / Bowtie (BW transform of the DB)

FASTA

- Hash table of short words in the query sequence
- Go through DB and look for matches in the query hash (linear in size of DB)
- perl: \$where{"ACT"} = 1,45,67,23....
- K-tuple determines word size (k-tup 1 is single aa)
- by Bill Pearson

<u>Join together query</u> <u>lookups into</u> <u>diagonals and then</u> <u>do a full alignment</u>

JP = Joining penalty

- Altschul, S., Gish, W., Miller, W., Myers, E. W. & Lipman, D. J. (1990). Basic local alignment search tool. *J. Mol. Biol.* **215**, 403-410
 Blast
- Indexes query
- Starts with all overlapping words from query
- Calculates "neighborhood" of each word using PAM matrix and probability threshold matrix and probability threshold
- Looks up all words and neighbors from query in database index
- Extends High Scoring Pairs (HSPs) left and right to maximal length
- Finds Maximal Segment Pairs (MSPs)
 between query and database
- Blast 1 does not permit gaps in alignments

BLAST: Basic Local Alignment Search Tool

DB

- Extend hash hits into High Scoring Segment Pairs (HSPs) ٠
- Stop extension when total score doesn't increase
- Extension is O(N). This takes most of the time in BLAST ٠

BLAST: Basic Local Alignment Search Tool

- In simple BLAST algorithm, find best scoring segment in each DB sequence
- Statistics of these scores determine significance

Short read alignment to a reference genome

- BLAT
- Burrows-Wheeler transform

<u>BLAT</u>

- "BLAST-like alignment tool"
- created by Jim Kent (UCSC) during assembly of the human genome
- Where BLAST builds an index of the query sequence, BLAT builds an index of the database.
 - Obviously, this will scan more quickly through the DB at the expense of building a huge hash table of the DB initially
 - DB index non-overlapping, potentially sacrificing some sensitivity for decreased memory usage

Burrows Wheeler Transform

- What's next: more sophisticated ways of organizing the genome pre-search to speed things up beyond building the DB hash table as in BLAT
- High Level
 - Build a BWT of the genome (cyclically permuting, then sorting, then compressing)
 - Then build a prefix tree of this
 - ◊ Take each read and search along the prefix tree in linear time
 - Reverse the transform to find the location of the read in the genome from its position in the prefix tree.

Burrows Wheeler Transform

- BWT is a reversible permutation of the characters in a string X
- 1. build matrix of cyclic rotations of X
- 2. sort matrix alphabetically

example:	X = acaacg
0 acaacg\$	6 \$acaacg
1 caacg\$a	2 aacg\$ac
2 aacg\$ac	0 acaacg\$
3 acg\$aca	=> 3 acg\$aca
4 cg\$acaa	1 caacg\$a
5 g\$acaac	4 cg\$acaa
6 \$acaacg	5 g\$acaac

Burrows Wheeler Transform

- BWT is a reversible permutation of the characters in a string X
- build matrix of cyclic rotations of X
- 2. sort matrix alphabetically
- 3. Extract
 - last column L of BWT matrix
 - position I of original string X in matrix

Speed v Sensitivity Tradeoff

PSI Blast as a form of Semi-supervised learning

What sequence alignment algorithms need to be designed next?

A couple of important problems:

 rapidly align a personal genome to a reference population of human genomes

◊ with clinical turn-around time; with privacy => encryption?

- 3rd generation sequencers: long, error-prone reads
 - $\diamond\,$ useful as scaffolds mixed with more accurate, cheaper short reads
